Computing with formulas

FC CK0030 2018.1

A formula

A formula

The vertical motion of a ball thrown up in the air

We can set up a mathematical model for the motion of the ball

• From Newton's second law of motion

The vertical position of the ball, called y, varies with time t

$$y(t) = v_0 t - \frac{1}{2} g t^2 \tag{1}$$

 $\sim v_0$ is the initial velocity of the ball

 $\rightarrow g$ is the acceleration of gravity

 \sim t is time

The y axis is chosen such that the ball starts from y = 0 at t = 0

A formula (cont.)

The time for the ball to move upwards and return to the ground again

We are interested in the solutions to equation y(t) = 0

$$v_0 t - \frac{1}{2} g t^2 = t (v_0 - \frac{1}{2} g t) = 0$$

$$\sim \begin{cases} t = 0 \\ t = 2 \frac{v_0}{g} \end{cases}$$
(2)

The ball returns to ground level in $2v_0/g$ (seconds)

We can focus in the interval $t \in [0, 2v_0/g]$

Programs and programming

Our task is to create programs/code and run it

There are three main types of tools for writing Python code

- A plain text editor
- An IPython notebook
- An integrated development environment (IDE) with a text editor

Remarl

What you choose depends on how you access Python

There are various possibilities

- Access a plain installation on your own computer
- Access a pre-installed environment (distribution)
- Access Python in a cloud service

Type conversion

Programs and programming (cont.)

We must express formulas in terms of symbols called variables

• Rather than numerical values

Definition

Variables

In Python, variables are defined by setting a name (here v0, g, t, or y) equal to a numerical value or an expression involving already defined variables

Most programming languages, Python included, can use variables

Computing with formulas

FC CK0030 2018.1

FC CK0030 2018.1

Variables

Variables and reserved words

Computing with formulas FC CK0030 2018.1

Variables

Variables and reserved words (cont.)

$$y(t) = v_0 t - \frac{1}{2}gt^2$$

With long variables names, the code for evaluating the formula got long

- We broke it into two lines (the backslash \ at the end of the line)
- Make sure there are no blanks after the backslash

Computing with formulas

FC CK0030 2018.1

Variables

Variables and reserved words

Variable names can contain

- Any lower or upper case letter of the alphabet (A, a, B, b, ...)
- Numbers from 0 to 9 (but first character cannot be a number)
- Underscore (_)

Python distinguishes between upper and lower case letters

- Variable X is different from variable x
- Variable Xx is different from xX

Computing with formulas

FC CK0030 2018.1

Variables

Variables and reserved words (cont.)

Long names explain well what they represent

Though checking correctness of the formula for y became harder

• (Than in the program using v0, g, t, and y0)

FC CK0030 2018.1

Integer division
Arithmetic operato

functions Examples

Interactive computing

Type conversion IPython

Variables and reserved words (cont.)

A standard convention is to have variable names with lower case letters

• (Then, words are separated by an underscore)

Example

Whenever the variable represents a mathematical symbol, we use it

- v_0 in mathematics becomes v_0 in the program
- y in mathematics becomes y in the program

Resemblance between math symbols and variables names is important

- → Easy reading of the code
- → Errors detection

Definition

Printf syntax (from function printf in the C programming language)

Output from a print statement, plus number formatting

The oldest and most widely used technique is printf formatting/syntax

- The printf syntax is used in a lot of other programming languages
- It is easy to learn and very convenient and flexible to work with
- The syntax of printf formatting may look awkward

Computing with formulas

FC CK0030 2018.1

Comments, text and number formats (cont.)

print 'At t=%g s, the height of the ball is %.2f m.' % (t, y)

We have two 'slots', thus two variables must be inserted into the slots

The relevant syntax is to list the variables inside parentheses after the string

- The variables' list is separated from it by a percentage symbol
- \sim % (t, y)

The first variable, t, goes into the first 'slot' with format specification %g

- The percentage sign marks the slot
- The following character, g, is the chosen format specification
- The g format instructs the real number to be compactly written

The next variable, y, goes into the second 'slot' with format .2f

- The .2f format instructs the real number is with two decimal digits
- → (The f in the .2f format stands for floating-point number)

Comments, text and number formats (cont.)

There are many available ways to specify formats

e writes a number in scientific notation

- A number between 1 and 10 followed by a power of 10
- $(1.2432 \cdot 10^{-3}, \text{ as } 1.2432\text{e-03})$
- Capital E in the exponent is possible: Replace e by E (1.2432E-03)

For decimal notation we use letter f (as in %f)

- The output number appears with digits before and/or after a comma
- (0.0012432 instead of 1.2432E-03)

It is possible to specify the format in some very sophisticated manner

Example

 \sim 10.4f

→ 14.6E

The first case: A float written in decimal notation

• 4 decimals in a field of width equal to 10 characters

The second case: A float written in scientific notation

• 6 decimals in a field of width equal to 14 characters

CK0030 2018.1

Comments, text and numbers formatting

Comments, text and number formats (cont.)

Format	Explaination
%s	A string
%d	An integer
%0xd	An integer in a x-width field, padded with leading zeros
%f	Decimal notation with six decimals
%e	Compact scientific notation, e in the exponent
%E	Compact scientific notation, E in the exponent
%g	Compact decimal or scientific notation, with e
%G	Compact decimal or scientific notation, with E
%xz	Format z right-adjusted in a x-width field
%-xz	Format z left-adjusted in a x-width field
%.yz	Format z with y decimals
%x.yz	Format z with y decimals in a x-width field
%%	The percentage sign

Computing with formulas

FC CK0030 2018.1

numbers formatting

Comments, text and number formats (cont.)

```
2 g = 9.81
               3 t = 0.6
               y = v0*t - 0.5*g*t**2
               7 print """
              8 At t=%f s, a ball with
               9 initial velocity v0=%.3E m/s
Arithmetic operators 10 is located at the height %.2f m.
              11 """ % (t, v0, y)
```

A triple-quoted string, started and ended by three single/double quotes

Triple-quoted strings are used for text that spans several lines

- t is printed in the f format (by default six decimals)
- \bullet v0 is written in the .3E format (three decimals and the number spans as narrow field as possible)
- y is two decimals in narrow decimal notation, .2f

- \bullet v0 is written in the .3E format (three decimals and the number spans as narrow field as possible)
- y is two decimals in narrow decimal notation, .2f

FC CK0030 2018.1

Comments, text and numbers formatting

Comments, text and number formats (cont.)

Format string syntax

It offers all the functionalities available with the printf format

• (And much more, through a different syntax)

We illustrate this syntax on the one-line output that was used earlier

```
print 'At t={t:g} s, the height of the ball is {y:.2f} m.' \
2 .format(t=t, y=y)
```

- Slots are denoted by curly braces (rather than a percentage sign)
- Variable are listed with an optional colon and format specifier
- Variables and their values are listed at the end of the statement
- Slots have names (the sequence of variables is not important)

with formulas

FC CK0030 2018.1

Computing

numbers formatting

Comments, text and number formats (cont.)

The newline character

We can also use ordinary single-quoted strings and a special character

- The special character indicates where line breaks should occur
- The special character is $\setminus n$ (a backslash followed by letter n)

```
1 print """y(t) is
2 the position of
3 our ball."""
5 print 'y(t) is\nthe position of\nour ball'
```

The two print statements have identical output

```
y(t) is
2 the position of
3 our ball.
```

Computing with formulas

FC CK0030 2018.1

Comments, text and numbers formatting

Comments, text and number formats (cont.)

At times, we want to write out text that spans several lines

```
print """
At t={t:f} s, a ball with
initial velocity v0={v0:.3E} m/s
is located at the height {y:.2f} m.
""".format(t=t, v0=v0, y=y)
```

We can obtain such an output by using triple-quoted strings

Remark

Many computer languages (..., Fortran, C, C++, Java, and Python 2.x) interpret a/b as integer division, if both operands a and b are integers

Suppose that either a or b are real (floating-point) numbers

- \rightarrow Then, a/b implies the standard mathematical division
- → (Float division)

Other languages (..., MATLAB and Python 3.x) interpret a/b as float division even if both operands are integers

• (or complex division if any of the operands is a complex number)

Integer division

Definition

Float division is what you expect from standard arithmetics

• 9/5 becomes 1.8 in decimal notation

Integer division a/b with integers a and b is an integer c

• It is the largest integer c such that bc < a

```
\rightarrow 9/5 is 1, as 1 \cdot 5 = 5 \le 9 and 2 \cdot 5 = 10 > 9
```

$$\rightarrow 1/5$$
 is 0, as $0 \cdot 5 \le 1$ and $1 \cdot 5 > 1$

Integer division (cont.)

The issue with our program is in the coding of the formula (9/5)*C + 32

```
C = 21
F = (9/5)*C + 32
print F
```

First, 9/5 is calculated (Python interprets 9 and 5 as integers)

- 9/5 is thus interpreted as a division between two integers
- Python chooses by default integer division, returning 1

Then, 1 is (normally) multiplied by C, giving 21

- 21 and 32 are added
- 53 is returned
- → (Wrong result)

with formulas FC CK0030 2018.1

Computing

Objects in Python

Rounding errors

Similarly, in C = 21.0, Python recognises number 21.0 as a real number

C = 21.0

It creates a **float** (for floating-point) **object** holding the value 21.0

• The variable C is the variable name of this float object

Computing with formulas

FC CK0030 2018.1

Objects in Python

Objects in Python

Consider a very general assignment statement like C = 21

• Python interprets number 21 as an integer

It creates an int (for integer) object holding the value 21

- The variable C acts as variable name
- This name labels the int object as C

Objects in Python (cont.)

Computing with formulas

FC CK0030 2018.1

Objects in Python

The key issue is that 21 and 21.0 are identical numbers in mathematics In Python,

- 21 gives an int object
- 21.0 gives a float object

FC CK0030 2018.1

Objects in Python

Rounding errors

Objects in Python (cont.)

Any (Python) assignment statement has the general form

- Variable name, on the left-hand side
- An object, on the right-hand side

```
1 C = 21
```

```
v0 = 5
2 g = 9.81
```

3 t = 0.6

5 y = v0*t - 0.5*g*t**2

Objects in Python

Objects in Python (cont.)

print 'A text with an integer %d and a float %f' % (2, 2.0)

A str (for string) object, without a name, is first created from 'the text between quotes' and then the str object is printed using print command

We can alternatively do this in two, sequential, steps

- s = 'A text with an integer %d and a float %f' % (2, 2.0)

Computing with formulas

FC CK0030 2018.1

Objects in Python

Objects in Python (cont.)

At this point, it is not requested to know now what an object exactly is

As initial simplification, one can think of an int object as a collection

- It is like a storage box, with some information about an integer
- The information is stored within the computer's memory
- The variable name C is used to access this information

There are various object types, some are pre-built some are user-defined

• Objects may contain a lot of data, not just integer/real numbers

Avoiding integer division

We must be careful to avoid integer division when coding math formulas

When a program is asked to implement an integer division

• A double forward-slash (//) should be used as division operator This is Python's way of explicitly indicating integer division

Remark

Python 3.x has no problem with unintended integer division

• Only with Python 2.x (and other languages)

There are several ways to avoid integer division with the plain (/) operator

Computing with formulas

Type conversio

Avoiding integer division (cont.)

A more widely used method, common also to other programming languages

→ Force one of the operands to be a float object

Example

```
1 F = (9.0/5)*C + 32
2 F = (9/5.0)*C + 32
3
4 F = float(C)*9/5 + 32
```

In the first two lines, one of the operands is written as a decimal number

• This implies a float object, and therefore float division results

In the last line, float(C)*9 means (float times int)

• This results in a float object, and thus float division is implicit

Evaluating mathematical functions

Standard mathematical formulas frequently involve common functions

• sin, cos, tan, sinh, cosh, exp, log, ...

On a pocket calculator you have special buttons for such functions

• Similarly, in a language you have ready-made functions

Remark

In principle, one could write his/her own program for evaluating

• Say, the $\sin(x)$ function

How to do it efficiently is often a non-trivial task

Experts have worked on such problem for decades

- They implemented their best recipes
- These codes should be (are) re-used

Example

Consider the program for the vertical position of the ball

```
1 v0 = 5

2 g = 9.81

3 t = 0.6

4 y = v0*t - 0.5*g*t**2

5 print y
```

It can be fully re-typed line-by-line in the Python shell

```
1 >>> v0 = 5

2 >>> g = 9.81

3 >>> t = 0.6

4 >>> y = v0*t - 0.5*g*t**2

5 >>> print y

6 1.2342
```

The shell

Type conver

The shell (cont.)

The next step is to re-compute y, with the new v0 value

- Hit the arrow-up key (↑) multiple times to recover the statement where y is assigned
- Press Return
- Write y or print y to see the result

We get two slightly different results

- y prints out all the decimals stored in the computer (16)
- print y prints out y with fewer decimals, standard format

The shell

Type conversi

The shell (cont.)

We can easily calculate the y value corresponding to another v0 value

- Hit the arrow-up key (1), to recover previous statements
- Repeat pressing \uparrow , until the v0 = 5 statement shows up
- You can then edit the relative line

```
1 >>> v0 = 6 # It was: v0 = 5
```

- Press Reurn, to execute this statement
- To check the new value of v0 either type v0 or print v0

```
1 >>> v0
2 6
34 >>> print v0
5 6
6
7 >>> print y # Old, needs be re-computed
1 .2342
```

Remar

Computations on a computer often suffer from rounding errors

• The present calculation is no exception

The correct answer is 1.8342

Rounding errors led to a number that is incorrect

- The error is in the 16th decimal
- The error is $4 \cdot 10^{-16}$

FC CK0030 2018.1

Rounding errors

Type conversion

Type conversion Interactive computing

Computing with formulas FC CK0030 2018.1

Type conversion

Type conversion (cont.)

Let us create some int object C

Let us check its type with type(C)

→ Function type

>>> C = 21

>>> type(C)

<type 'int'>

>>> C

We convert the int object C to a corresponding float object

→ Function float

>>> C = float (C)

>>> type(C) <type 'float'>

5 >>> C

6 21.0

type conversion

Computing with formulas

FC CK0030 2018.1

Type conversion

Type conversion

Work w/o bothering about the type of objects variables refer to

- Yet, we encountered a serious problem with integer division
- Important to be careful about the involved types of objects

The interactive shell is useful for exploring types (the type function)

Computing with formulas

FC CK0030 2018.1

Type conversion

Type conversion (cont.)

Statement C = float(C) creates a new object, C

→ From the original one, C

→ It binds it to the same name C

The new object is also referred to by the name C

After the statement, variable C refers to a different object

• Original int object, value 21, becomes unreachable

IPython

IPython

There are several improvements of the standard Python shell

• You need to have ipython installed

Typing ipython in a terminal window starts the shell

```
Terminal > ipython
Python 2.7.9 (default, Jun 29 2016, 13:08:31)
Type "copyright", "credits" or "license" for more information.

IPython 2.3.0 -- An enhanced Interactive Python.
? -> Introduction and overview of IPython's features.

'Aquickref -> Quick reference.
help -> Python's own help system.
object? -> Details about 'object', use 'object??' for extra
details.

In [1]:
```

FC CK0030 2018.1

IPython

IPython (cont.)

The (default) prompt in ipython is not > > but In [X]:

• X is the number of the present input command

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

On Windows you may, as alternative to starting IPython from a DOS or PowerShell window, double click on the IPython icon or use Start menu

- You must move to the folder where your program is located
- If ball2.py is in the folder div under My Stuff of user me
- (This is done by the os.chdir, change directory, command)

```
2 In [2]: os.chdir(r'C:\Documents and Settings\me\My Stuff\div')
3 In [3]: run ball2.py
```

- Note the r before the quote in the string
- Required to let a backslash (\) really mean the backslash character

Computing with formulas

FC CK0030 2018.1

IPython

iPython (cont.)

Running programs

```
Terminal > ipython
  Python 2.7.9 (default, Jun 29 2016, 13:08:31)
  Type "copyright", "credits" or "license" for more information.
  IPython 2.3.0 -- An enhanced Interactive Python.
           -> Introduction and overview of IPython's features.
  %quickref -> Quick reference.
  help
         -> Python's own help system.
9 object? -> Details about 'object', use 'object??' for extra
              details.
12 In [1]: run ball2.py
13 1.2342
```

The command requires that you have cd'ed to the folder with ball2.py

Computing with formula

FC CK0030 2018.1

IPython

IPython (cont.)

You may frequently have to type the os.chdir command in ipython

This and other commands can be suitably placed in a startup file

- → A file that is automatically executed when you launch ipython
- → To create one from Terminal, ipython create profile

FC CK0030 2018.1

Rounding errors

IPython

IPython (cont.)

Inside ipython you can invoke any operating system command

This allows to navigate the filesystem with Unix/Windows commands (cd)

• (Instead of Python's, os.chdir)

```
1 In [1]: cd C:\Documents and Settings\me\My Stuff\div
```

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

It is recommended to run all Python programs from inside ipython

- ipython can help examine the state of variables and locate bugs
- (When something goes wrong)

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

Suppose that some Python variables have the same name as an OS command

• (date=30)

The OS command must be called with an exclamation mark (!) in front

• (!date)

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

- → To execute a program in ipython, type run before program name
- → To run a program in a Terminal, python prior to program name

FC CK0030 2018.1

Examples

Rounding errors

IPython

IPython (cont.)

Output from statements or expressions in ipython are preceded by Out [X]

• X is the command number of the last In [X] prompt

mands are run, the output is from the OS itself

When programs are executed, as with the run command or when OS com-

• In this case, the output is not preceded by any Out [X] label

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

Remember that the output from input In [1] was 1.2342

We can now refer to it by an underscore

We can also perform operations on it

• Say, we multiply it by 10

```
1 In [2]: _*10
2 Out [2]: 12.341999999999999
```

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

Output recovery

Outputs (Out [X]) from previous statements in ipython are available/usable

They are in variables of the form _iX (underscore _, i, and a number X)

X is 1 for the last statement, 2 for the second last statement, and so forth

• Short forms are _ (for _i1), __ (for _i2), and ___ (for _i3)

Computing with formulas

FC CK0030 2018.1

IPython

IPython (cont.)

Command recovery

The command history is navigated by typing Ctrl+p

- \uparrow for going backward
- Ctrl+n or \Downarrow for going forward

Any command you hit can be edited and re-executed

- Also commands from previous sessions
- (They are in the history)
